

## NAME

IO::Select - OO interface to the select system call

## SYNOPSIS

```
use IO::Select;

$s = IO::Select->new();

$s->add(\*STDIN);
$s->add($some_handle);

@ready = $s->can_read($timeout);

@ready = IO::Select->new(@handles)->can_read(0);
```

## DESCRIPTION

The `IO::Select` package implements an object approach to the system `select` function call. It allows the user to see what IO handles, see *IO::Handle*, are ready for reading, writing or have an exception pending.

## CONSTRUCTOR

`new ( [ HANDLES ] )`

The constructor creates a new object and optionally initialises it with a set of handles.

## METHODS

`add ( HANDLES )`

Add the list of handles to the `IO::Select` object. It is these values that will be returned when an event occurs. `IO::Select` keeps these values in a cache which is indexed by the `fileno` of the handle, so if more than one handle with the same `fileno` is specified then only the last one is cached.

Each handle can be an `IO::Handle` object, an integer or an array reference where the first element is an `IO::Handle` or an integer.

`remove ( HANDLES )`

Remove all the given handles from the object. This method also works by the `fileno` of the handles. So the exact handles that were added need not be passed, just handles that have an equivalent `fileno`.

`exists ( HANDLE )`

Returns a true value (actually the handle itself) if it is present. Returns undef otherwise.

`handles`

Return an array of all registered handles.

`can_read ( [ TIMEOUT ] )`

Return an array of handles that are ready for reading. `TIMEOUT` is the maximum amount of time to wait before returning an empty list, in seconds, possibly fractional. If `TIMEOUT` is not given and any handles are registered then the call will block.

`can_write ( [ TIMEOUT ] )`

Same as `can_read` except check for handles that can be written to.

`has_exception ( [ TIMEOUT ] )`

Same as `can_read` except check for handles that have an exception condition, for example pending out-of-band data.

`count()`

Returns the number of handles that the object will check for when one of the `can_` methods is called or the object is passed to the `select` static method.

`bits()`

Return the bit string suitable as argument to the core `select()` call.

`select ( READ, WRITE, EXCEPTION [, TIMEOUT ] )`

`select` is a static method, that is you call it with the package name like `new`. `READ`, `WRITE` and `EXCEPTION` are either `undef` or `IO::Select` objects. `TIMEOUT` is optional and has the same effect as for the core `select` call.

The result will be an array of 3 elements, each a reference to an array which will hold the handles that are ready for reading, writing and have exceptions respectively. Upon error an empty list is returned.

## EXAMPLE

Here is a short example which shows how `IO::Select` could be used to write a server which communicates with several sockets while also listening for more connections on a listen socket

```
use IO::Select;
use IO::Socket;

$lsn = new IO::Socket::INET( Listen => 1, LocalPort => 8080 );
$sel = new IO::Select( $lsn );

while( @ready = $sel->can_read ) {
    foreach $fh ( @ready ) {
        if( $fh == $lsn ) {
            # Create a new socket
            $new = $lsn->accept;
            $sel->add( $new );
        }
        else {
            # Process socket

            # Maybe we have finished with the socket
            $sel->remove( $fh );
            $fh->close;
        }
    }
}
```
