

NAME

base - Establish an ISA relationship with base classes at compile time

SYNOPSIS

```
package Baz;
use base qw(Foo Bar);
```

DESCRIPTION

Unless you are using the `fields` pragma, consider this module discouraged in favor of the lighter-weight `parent`.

Allows you to both load one or more modules, while setting up inheritance from those modules at the same time. Roughly similar in effect to

```
package Baz;
BEGIN {
    require Foo;
    require Bar;
    push @ISA, qw(Foo Bar);
}
```

`base` employs some heuristics to determine if a module has already been loaded, if it has it doesn't try again. If `base` tries to `require` the module it will not die if it cannot find the module's file, but will die on any other error. After all this, should your base class be empty, containing no symbols, it will die. This is useful for inheriting from classes in the same file as yourself, like so:

```
package Foo;
sub exclaim { "I can have such a thing?!" }

package Bar;
use base "Foo";
```

If `$VERSION` is not detected even after loading it, `<base>` will define `$VERSION` in the base package, setting it to the string `-1`, set by `base.pm`.

`base` will also initialize the fields if one of the base classes has it. Multiple inheritance of fields is **NOT** supported, if two or more base classes each have inheritable fields the 'base' pragma will croak. See *fields*, *public* and *protected* for a description of this feature.

The base class' `import` method is **not** called.

DIAGNOSTICS

Base class package "%s" is empty.

base.pm was unable to require the base package, because it was not found in your path.

Class 'Foo' tried to inherit from itself

Attempting to inherit from yourself generates a warning.

```
package Foo;
use base 'Foo';
```

HISTORY

This module was introduced with Perl 5.004_04.

CAVEATS

Due to the limitations of the implementation, you must use `base` *before* you declare any of your own fields.
